

Question 1 (Most Important)

You answered:

Multiple cycles for same item = NO

Multiple cycles simultaneously = NO

But in actual manufacturing:

Example:

- Customer requirement = 50,000 Nos
- Today RS = 5,000
- Tomorrow RS = 7,000
- Next week RS = 10,000

Then How do you identify and track daily RS against the same customer/item?

A. Every RS is independent

B. One customer/item remains open and multiple RS are generated against it

C. Something else

This answer will determine the entire NO_QTY architecture.

Question 2

You says:

RS prepared by Store Department.

Then When Store creates an RS, what quantity is entered?

A. Customer daily schedule quantity

B. Production capacity quantity

C. Available RM based quantity

D. Management decided quantity

E. Combination

This determines how WO generation should work.

Question 3

This is the biggest planning question.

You says:

Monthly schedule received from customer.

Daily triggers received later.

Example:

Customer monthly schedule = 100,000

Daily trigger:

- Day 1 = 5,000
- Day 2 = 4,000
- Day 3 = 8,000

Then what do you actually dispatch against?

- A. Monthly schedule
- B. Daily trigger
- C. Whichever is lower
- D. Other

This affects dispatch planning and production planning.

Question 4 (Jobwork)

You answered:

One item to multiple jobworkers = not answered

One jobworker to multiple items = NO

This answer looks unusual.

Can the same FG item go to:

- Jobworker A for plating
- Jobworker B for machining
- Jobworker C for assembly

or only one jobworker ever?

This affects jobwork design significantly.
